Klossiella muris

Prevalence

- Rarely observed in laboratory mice
- Common in wild mice

Significance

- Infected mice exhibit decreased oxygen consumption and endurance
- Impairs metabolic capabilities under certain environmental conditions

Disease

- Gametogeny and sporogony in epithelial cells lining convoluted tubules (sporocysts appear as eosinophilic spherical structures in cytoplasm) – minimal inflammation
- Also observed in capillaries and arterioles of lungs, liver, spleen, and thymus

Transmission

- Infection (Renal Coccidiosis) by ingestion of sporocytes with hematogenous spread to glomerular capillaries and asexual reproduction (multiple fission):
 - o Asexually replicating forms rupture from glomeruli into Bowman's space and to renal tubules and invade tubular epithelium
 - o Infective sporocytes released from ruptured host cells, into urinary bladder and into the environment

Isolation and Diagnosis

- Identifying replicating forms histologically in the glomerular endothelium or renal tubular epithelium
- Routine hematoxylin-eosin staining
- Examining pellet of centrifuged urine

Prevention and Control

- Coccidiostats reduce histological incidence
- Rederived, barrier-maintained mouse colonies will not be infected
